A: The solution is to not use the iptables-restore-drop.sh script at all. The script adds a rule for each IP to the firewall that the script expects to find on the router interface that IP is on. The script thus expects that the router interface number is 1, and that IP 1 is on that interface, and adds a rule for each of those. The solution is to just use iptables and the standard kernel interface management code. The script only adds unnecessary rules to the router interface if iptables is to be used for any other reason.
